Abstract
The efficient nanocomposite of CoFe$_2$O$_4$ diatomite for electromagnetic microwave adsorption was assembled by CoFe$_2$O$_4$ nanoparticles (NPs) and diatomite via a simple citric acid-nitrate sol-gel auto-combustion method. The electronic microscopy results show that the magnetic CoFe$_2$O$_4$ NPs are uniformly dispersed in the surface and porous structure of diatomite to form stable CoFe$_2$O$_4$/diatomite nanocomposite. The magnetic and dielectric properties with various mass ratios of CoFe$_2$O$_4$ to diatomite was investigated. It was showed that nanocomposite of CoFe$_2$O$_4$/diatomite has strong superparamagnetic and electromagnetic microwave absorbing properties with optimized conditions of coercive force of 837.07 Oe, the saturation magnetization of 96.5 emu/g, and the remanence ratio (Mr/Ms) of 0.52, respectively. The maximum reflection loss is -12dB, and <-10dB frequency ranges from 10Hz to 12Hz when the ratio of CoFe$_2$O$_4$ to Diatomite is 1:10. The results indicate that CoFe$_2$O$_4$/diatomite composites can be used as the highly efficient microwave absorption materials, which expanded the application field of diatomite-based functional nanomaterials.

Keywords: diatomite; CoFe$_2$O$_4$; electromagnetic microwave adsorbent, nanocomposite, porous minerals

1. Introduction

With the rapid development of electronic technologies, the electromagnetic interference (EMI) caused by electromagnetic microwaves (EMW) is becoming serious problems. The harmful electromagnetic radiation (EM radiation or EMR) not only affects sensitive electronic equipment, but also harmful to human health [1, 2]. In order to reduce the impact of EMW, scientists pay much attention to explore and design high-performance electromagnetic wave absorbing materials with properties of lightweight, wide frequency range and low cost [3-7]. The EM absorbing material has been applied not only

in the stealth technology of military, but also the ordinary commercial productions in all aspects to effectively reduce the reflection and transmission of EMW by converting EM into thermal energy [7-9]. Generally, the typical electromagnetic wave absorbents are constructed by embedding an EMW adsorbent into a host matrix, whose microwave adsorbing properties are primarily determined by the suspended materials.

Ferrite is one of the main frequently used microwave absorbing materials, which can efficient absorbing harmful electromagnetic radiation [10, 11]. Spinel ferrite (MFe \(_2\)O\(_4\), M = Mn, Mg, Co, Cu, Zn, Ni, Fe etc.) exhibits adjustable saturation magnetization, excellent chemical stability, low real dielectric constant and high magnetic loss. Among these spinel ferrites, CoFe\(_2\)O\(_4\) received particular attention due to their remarkable properties, which include a moderate saturation magnetization, excellent chemical stability, and high mechanical hardness [12]. On the basis of these characteristics, CoFe\(_2\)O\(_4\) ferrite can be used as a powerful EMW adsorption material [13]. However, bulk magnet CoFe\(_2\)O\(_4\) ferrite has disadvantages of high density, narrow bandwidth and large absorber thickness, which restricted their applications. In order to overcome these disadvantages and improve its absorbing efficiency, one effective strategy is to immobilize ferrite nanoparticles (NPs) on high physical and chemical stability porous supports such as activated carbon [14], silica [15, 16] and grapheme [17, 18], which realized to wide absorbing band (below -10 dB), lightweight, corrosion resistance and high temperature resistance [3, 19-21].

Diatomite is a low-cost silicate mineral composed by silica microfossils of aquatic algae with high permeability and porous structure that possesses the properties of large surface area, small particle size, and remarkable thermal stability [22, 23]. Therefore, diatomite is one of the most promising supports for dielectric materials [9, 24], which explored for preparation of EMW adsorbing nanocomposite. It has technical challenges for general utilization of the coal-derived diatomite due to its high contents of organic matters and iron in diatomite industrial of China. Thus, the large-scale sustainable utilization of coral-derived diatomite as a porous support for preparation of EMW adsorbing materials was taken into consideration. In the presented work, the CoFe\(_2\)O\(_4\)/diatomite nanocomposite for EMW adsorbing was prepared by citric acid-nitrate sol-gel auto-combustion method using coal-derived diatomite as support. The electromagnetic properties of the as-prepared nanocomposites were studied in the frequency range of 0–18GHz.

### 2. Materials and methods

#### 2.1 Materials

The experimental used diatomite is the purified from the Xianfeng coal mine of China. CoCl\(_2\).6H\(_2\)O of analysis grade was purchased from the pharmaceutical group of chemical reagents; FeCl\(_3\).6H\(_2\)O, PVP, NaOH, and anhydrous ethanol were obtained from Chengdu Kelon Chemical Reagent company. All other chemicals or reagents were used without further purification.

#### 2.2 Preparation of CoFe\(_2\)O\(_4\)/diatomite nanocomposite

##### 2.2.1 Purification of diatomite

Generally, 250 g of diatomite was added into water to prepare aqueous suspension with water-diatomite ratio of about 20:1 (water depth: 40 cm). Then, the upper aqueous layer of 5 cm was taken out after stirring at a suitable speed (300 rpm) for 30 min. The remaining sample was centrifuged to obtain pellets of purified diatomite. The wetly pellets of purified diatomite was dried by common muffle furnace at 70 °C for experiments.

##### 2.2.2 Preparation of CoFe\(_2\)O\(_4\) NPs

For sintering was chosen based on the SiO\(_2\)-Al\(_2\)O\(_3\) phase diagram [17], waiting for the following phase transitions: 450 °C – kaolinite–metakaolinite; 575 °C.

##### 2.2.3 Preparation of nanocomposite

The purified diatomite was added into above mentioned first preparation process of CoFe\(_2\)O\(_4\) NPs for preparation of suspension with various ratios. The as-prepared samples after auto-combustion process was homogenous dispersed into ethanol, and then ultrasonic treated 20 min and shaken at room temperature for 5h. The as-prepared samples were finally dried in a vacuum oven at room temperature overnight for characterization. Finally, the nanocomposite samples were calcined at different temperatures for 2 h in muffle furnace.

#### 2.3 Characterization

The mineral phase characterization was carried out using X’Pert Pro X-ray diffractometer (XRD) from PA Nalytical, Netherlands. The ULTRA55 field emission scanning electron microscopy (FE-SEM) and Libra 200FE-type transmission electron microscopy (TEM) were used to observe the morphological characteristics. The magnetic characterizations were carried out using the BKT-4500Z high precision vibration sample magnetometer of Beijing Xinke GaoShan Technology Co., Ltd. An Agilent N5230C microwave network analyzer was used to analyze the microwave absorption characteristics of the material.

### 3. Results and discussions

#### 3.1 Morphological observations

The FE-SEM and TEM were used for characterizing the morphology of samples. Micrographs show the formation of spherical CoFe\(_2\)O\(_4\) NPs with average particle size of 40 nm (Fig. 1a, 1e). As shown in Figures 1b and 1f, the distinctive porous structures of the diatomite were occupied by CoFe\(_2\)O\(_4\)NPs. The elemental components of CoFe\(_2\)O\(_4\) NPs and CoFe\(_2\)O\(_4\)/diatomite nanocomposite (DCNC) were identified by EDX analysis (Fig. 1c, 1d). The EDX patterns qualitative confirmed the presence of Co, Fe and O in the DCNC.

#### 3.2 XRD characterization

The XRD characteristics of CoFe\(_2\)O\(_4\) NPs, DCNC and diatomite are show in Fig. 2. The diffraction peaks appeared at Bragg angles 2θ=20–18.3°, 30.1°, 35.4°, 37.1°, 43.1°, 53.4°,57.0°
and 62.6° corresponding to (111), (220), (311), (222), (422), (511) and (440) planes of CoFe$_2$O$_4$, respectively with $a=b=c=8.377$, by which confirmed the formation of cubic spinel structure. The natural diatomite is in the amorphous form without showing crystalline peaks. The diffraction peaks show small amount of impurities of magnetite Fe$_3$O$_4$ and Quartz. The XRD pattern of CDNC shows that CoFe$_2$O$_4$ is successfully compounded with diatomite.

The hysteresis graphs for CoFe$_2$O$_4$ NPs and DCNC are typical of the soft magnetic material. CoFe$_2$O$_4$ NPs exhibits significant ferromagnetic behavior with Hc of 837.07 Oe, Ms of 96.5 emu·g$^{-1}$, Mr of 49.9 and Mr/Ms of 0.52. It seems that existing strong ferromagnetic coupling among CoFe$_2$O$_4$ NPs, in which them ferromagnetically coupled together and behaving as magnetic nanochains rather than as individual NP [17]. As shown in Fig. 3, it is clear that the saturation magnetization of DCNC is much lower than the corresponding value of CoFe$_2$O$_4$ NPs. Lower saturation magnetization is contributed to the addition of non-magnetic diatomite to CoFe$_2$O$_4$ NPs. Therefore, from the aspect of engineering application, the magnetic properties of DCNC can be adjusted to meet the requirement of actual design by changing the compositions between diatomite and CoFe$_2$O$_4$ NPs.

### 3.4 Dielectric properties

The microwave dielectric properties of CoFe$_2$O$_4$ NPs and DCNC were measured at frequencies (0-18 GHz) by the microwave network analyzer. The electromagnetic properties are mainly characterized by two basic parameters\cite{4, 27} as described by Eq.(1) and Eq.(2):

\[ \varepsilon_r = \varepsilon' + i\varepsilon'' \]  \hspace{1cm} (1)

\[ \mu_r = \mu' + i\mu'' \]  \hspace{1cm} (2)

Where $\varepsilon'$ and $\varepsilon''$ are the real part or dielectric constant and imaginary part or dielectric loss of the complex dielectric permittivity. Where $\mu'$ and $\mu''$ are the real magnetic permeability and magnetic loss.

In addition, the dielectric loss tangent (tan $\delta$) characterizes the dielectric loss of a dielectric material after applying an
electric field. Where $\delta$ is dielectric loss angle. The electric loss tangent is determined by the complex permeability:

$$\tan \delta_E = \frac{\varepsilon''}{\varepsilon'}$$  \hspace{1cm} (3)

The magnetic loss tangent is determined by the complex permeability:

$$\tan \delta_M = \frac{\mu''}{\mu'}$$ \hspace{1cm} (4)

### 3.4.1 Dielectric properties

It is well known that the dielectric constant is the expression of the polarization capacity of the material. Dipoles, interfaces, ions and electron polarization favor dielectric loss. At lower frequencies, dipole and interfacial polarization are important for dielectric loss. However, ion and electron polarization make a most significant contribution to the dielectric loss at higher frequency[28]. Polarization and variation of dielectric constant in CoFe$_2$O$_4$ and its complexes may be related to changes of Fe$^{2+}$ and Fe$^{3+}$ concentrations [29]. Moreover, the dielectric constant of CoFe$_2$O$_4$ and its complexes depends on the amount of Fe$^{3+}$ in the microwave frequency because they are susceptible to polarization than Fe$^{3+}$ [30].

The dielectric properties of CoFe$_2$O$_4$ NPs, diatomite and DCNC are shown in Fig. 4 in the frequency range of 2–18GHz. The $\varepsilon'$ of the samples always show a rapid decline and then a small increase, and finally a downward trend. $\varepsilon''$ appears to fall and then rise and then fall again, finally in rising trend. At 4–6Hz, 7–9Hz Fig. 4a and Fig. 4b appear more obvious dielectric resonance peak. The values of $\varepsilon'$, $\varepsilon''$ in single CoFe$_2$O$_4$ are the smallest in the range of 2–18Hz. The value of $\varepsilon''$ fluctuates between 1.26–1.13 and the value of $\varepsilon''$ fluctuates in the range of 0.09–0.18. With the decrease in the mixing ratio of CoFe$_2$O$_4$ and diatomite, the values of $\varepsilon'$, $\varepsilon''$ have been significantly improved. When the ratio of CoFe$_2$O$_4$ to diatomite is 1:5, the values of $\varepsilon'$, $\varepsilon''$ are the largest and the best. The maximum values of $\varepsilon'$, $\varepsilon''$ are 1.47 and 0.18 respectively, and the minimum values are about 1.23 and 0.09 respectively. The peaks in the range of 4–6Hz are about 1.29 and 0.075 respectively, and the peaks in 7–9Hz are about 1.32 and 0.1. Significant relaxation peaks appeared at around 6GHz and 15GHz, indicating that there is dielectric relaxation in both CoFe$_2$O$_4$ NPsand composites [31] and the polarization is strong. But only when CoFe$_2$O$_4$ and diatomite ratio of 1:5 and 1:10, The values of $\varepsilon'$, $\varepsilon''$ are greater than a single diatomite and the effect is better after compositing. Although the composite of 1:10 is relatively smaller than that of 1:5, it is relatively close to that of 1:5. The maximum value of $\varepsilon'$ is about 1.44 and the minimum value is about 1.22 when the ratio of CoFe$_2$O$_4$ to diatomite is 1:10. And its peaks in 4–6Hz and 7–9Hz are about 1.29 and 1.31 respectively. Its value of $\varepsilon''$ is almost the same to the value of 1:5, so it is more economical in practical application. And when CoFe$_2$O$_4$ and diatomite ratio is 1:2, the values of $\varepsilon'$, $\varepsilon''$ are between single CoFe$_2$O$_4$ and single diatomite. Thus, the effect is general. The loss tangent represents the loss of the microwave absorbing material and supports the dominant contribution of conductivity to dielectric loss. It can be seen from the Fig. 4e that the value of a single diatomite is the largest and the value of single CoFe$_2$O$_4$ is the smallest, which is mainly because diatomite is a dielectric loss material and CoFe$_2$O$_4$ is electromagnetic loss material. As the ratio of CoFe$_2$O$_4$ to diatomite decreases, the loss tangent is also reduced.

### 3.4.2 Permeability properties

In the range of 2–18Hz, the values of $\mu'$ of each sample shows a trend of decreasing at first and then rising, and fluctuating in a small range. The value of $\mu''$ has a more complex change with a greater degree fluctuating. The value of $\mu''$ of a single CoFe$_2$O$_4$ is the largest in the range of 2–18Hz and the maximum is about 0.045, which is close to the ratio of CoFe$_2$O$_4$ to diatomite at 1:10. However, as the ratio of CoFe$_2$O$_4$ to diatomite increases, the value of $\mu''$ decreases at the same frequency. When the ratio of CoFe$_2$O$_4$ to diatomite is 1:2, the value of $\mu'$ is the smallest in the range of 2–18Hz and the minimum is about 0.92. The single diatomite is slightly larger than it. In addition, the value of $\mu''$ is the largest in the low frequency range whose maximum is about 0.045 but the single diatomite is the smallest and its minimum is about 0.015. In the high frequency range, the volatility is more complicated. The single diatomite is the largest in 12–14Hz and 16–18Hz and the peaks are about 0.023 and 0.015 respectively. Moreover, in 14–16Hz, the largest value
is 0.015 when the ratio of CoFe₂O₄ to diatomite is 1:10. It can be seen from Fig. 4d that the magnetic permeability fluctuates greatly with frequency, and multiple resonance peaks appear, indicating the presence of ferromagnetic resonance behavior [32]. Due to the influence of CoFe₂O₄ spinel structure on the anisotropy field, the magnetic field anisotropy causes a large change in magnetic permeability. The main source is that the unpaired electrons in the ferromagnetic medium use magnetic materials to absorb energy from the microwave magnetic field and cause magnetic energy loss. According to the analysis of magnetic loss tangent, in the low frequency range, the loss is the largest when the ratio of CoFe₂O₄ to diatomite is 1:2 and the performance is closer when the ratio of CoFe₂O₄ to diatomite is 1:5 and 1:10. In the High-frequency range, the ratio of CoFe₂O₄ to diatomite is 1:10 better than 1:5, and the loss angle tangent is greater.

In general, when the dielectric and magnetic properties of the composites are matched with each other, the microwave absorption effect will be better. Considering the economic rationality and the absorbing effect, when the ratio of CoFe₂O₄ to diatomite is 1:10, the dielectric dissipation effect of diatomite and the magnetic dissipation effect of CoFe₂O₄ NPs can be combined to achieve the best absorbing properties.

### 3.4.3 Microwave absorption properties

As shown in Fig. 5, the microwave absorption performances of the samples are basically the same, which have the best absorption effect when nearing 11 GHz. This phenomenon is consistent with the above analysis of the permeability. The porous structure of the diatomite as the matrix causes the electromagnetic wave traveling path to cause the formation of multiple internal reflections and multiple scattering, which significantly enhances the attenuation capability, thereby contributing to the enhancement of microwave absorption performance [33]. When the ratio of CoFe₂O₄ to diatomite is 1:2, the composite has the best absorbing effect. When the ratio of CoFe₂O₄ to diatomite is 1:10 and 1:5, the wave absorbing performance is the second. The peak is about -9dB in 4~6GHz. The range of <10Hz is between 10Hz and 12Hz and the maximum reflection loss is about -12dB. In addition, when the ratio of CoFe₂O₄ to diatomite is 1:10, the composite has the best absorbing effect whose maximum reflection loss is about -9dB ranging from 12 to 18GHz, while the maximum reflection loss of other materials is only about -7Hz. As shown in Table 2, it reflects the maximum reflectivity loss for each material. From the economic point of view, when the ratio of CoFe₂O₄ to diatomite is 1:10, the absorbing performance is close to that of CoFe₂O₄ and diatomite of 1:2 in the low frequency range. Moreover, in the high frequency range, the composite of 1:10 has the best absorption effect.

Therefore, the composite of 1:10 is most conducive to the promotion. It is worth noting that CoFe₂O₄ and its complex have two secondary absorption peaks near the 5 GHz and 15 GHz frequencies, which correspond to the minimum value of the sample loss tangent rather than the sub-peak corresponding to the loss tangent. The absorption peak has moved. In a word, the absorbing ability of the material is not only closely related to its permeability, but also has a significant relationship with the thickness of the absorbing plate, which will result in the left and right offset of peak positions of absorption peaks and values of loss tangent. Therefore, the wide peak value of the loss tangent will be of great importance to the expansion of absorbing capacity, so that the material can meet the requirements of multi-band and various thicknesses.

### 4. Conclusions

In summary, the DCNC of CoFe₂O₄/diatomite were fabricated via citric acid-nitrate sol-gel auto-combustion method. The FE-SEM and TEM observations confirmed that the magnetic NPs were uniformly dispersed in the surface and porous structure of diatomite to form stable DCNC. Magnetic measurements show that all samples are ferromagnetic, and that the Co³⁺ occupies the octahedral (B) site, will result in a reduction in the A-O-B super exchange interaction and a total of the magnetic properties of Fe²⁺ ions reduce. The microwave dielectric properties of the DCNC show that the dielectric and magnetic properties of the composites are optimized. The optimized best absorption performance of DCNC with ratio of CoFe₂O₄ to diatomite is 1:10 considering the economic rationality and the absorbing performances. In generally, our study shows a promising way for construction of diatomite-based functional nanomaterials.
